Conceptual Motivation

What we know:

- LLMs need require **frequent and continuous updates** to keep up with growing user **demands across diverse tasks**.
- Model Merging** has emerged as a **cost-effective** approach to combine the strengths of different models **without altering their underlying architecture**.

Model Evolution:

- LLMs can evolve to integrate new capabilities by **iteratively merging with one another**.

$$E(\theta^{(t)} | \theta^{(t-1)}, \theta^{(t-2)}, \dots, \theta^{(0)}) = E(\theta^{(t)} | \theta^{(t-1)}, \theta_{\text{merge}}^{(t)})$$

Question: How can we systematically select models for merging to achieve greater performance improvements?

Key Contributions

- Model Kinship:** Introduce a kinship metric to assess LLM similarity during merging, guiding auto-merging strategies.
- Empirical Analysis:** Evaluate iterative merging dynamics, highlighting multitask performance gains and stagnation, with insights from model kinship.
- Practical Strategies:** Propose Top-k Greedy Merging with model kinship to efficiently tackle merging optimization challenges.

Model Kinship

We need an **efficient metric** to evaluate the **overall capability difference** between models, without relying on a dataset for evaluation, **to estimate the outcome of future merges (high or low)**.

- Extract **delta parameter** δ_{target} of the target models.
- Calculate the **kinship** between **delta parameters**.

$$\delta_{\text{target}} = \theta_{\text{target}} - \theta_{\text{base}}$$

$$k = \text{sim}(\delta_1, \delta_2)$$

Parameter changes introduced through fine-tuning/iterative merging processes.

e.g. adopt **Pearson Correlation Coefficient** as similarity metric:

$$\text{sim}(\delta_i, \delta_j) = \frac{\text{cov}(\delta_i, \delta_j)}{\sigma_{\delta_i} \sigma_{\delta_j}} = \frac{\sum(\delta_i - \bar{\delta}_i)(\delta_j - \bar{\delta}_j)}{\sqrt{\sum(\delta_i - \bar{\delta}_i)^2} \sqrt{\sum(\delta_j - \bar{\delta}_j)^2}}$$

- Correlation between task capability difference and kinship**

Initial Analysis

Correlation Analysis of Model Kinship

Kinship Change Through Model Evolution Paths

Mutual Kinship of Candidate Models Through Evolution

Main Results

- Enhance the greedy merging strategy by **adding additional merges based on low model kinship**.

Table 2: Results of merging experiments comparing the vanilla greedy strategy and our proposed approach. The first three models serve as the foundation models in both experiments. **Note:** The model kinship experiment was terminated at generation 5, as it has already outperformed the greedy strategy by that point.

Greedy Strategy				+ Model Kinship

Stop improving

Findings:

- Merging low-kinship** models introduces novel weight variations, enabling continued iterative merging.
- Early stopping at high kinship** reduces resource consumption while maintaining performance.

Future works

- Advance **interpretability** by designing more **informative metrics** to explain model merging behavior.
- Explore **foundational theory** for **automated, self-evolving model merging pipelines**.
